

### BE280A Midterm Project Assignment

**Due Date:** Completed project (hard copy) is due at 1 pm on Wednesday, November 10, 2010 – please turn in at Room 1001 of the fMRI Center between 12 pm noon and 1 pm. In addition to the hard copy, please submit a PDF version of the report via e-mail by 3 p.m. on that day. Please send your e-mail to **both** the instructor and the TA.

For full credit, the subject line of your e-mail should read **BE280A09 Midterm Project**. The report filename should follow the following format `ct_{initials of partner 1}_{initials of partner 2}.pdf` – e.g. `ct_lk_pb.pdf`.

#### Guidelines:

- 1) Select a partner to work with.
- 2) Discussion of **general ideas** is encouraged between groups, however, each report submitted should reflect each group's own understanding of the material. Significant discussions with other groups should be given appropriate credit.
- 3) An electronic copy of the MATLAB code should also be submitted with the PDF of the report. The code file should be named in a similar fashion to the \*.pdf file, except with a \*.m extension.
- 4) Use a word-processing program to write the report, including all equations (no handwritten reports! Use an equation editor.). Neatness and clarity of exposition will play a **significant** role in the grading of the report. Other grading criteria include technical correctness and originality.
- 5) You may use external references (print or electronic). If you do so, please cite them at the end of your report.
- 6) Title and label the axes on all plots and images.
- 7) In addition to answering the questions below, please provide additional details and original insights as appropriate. If you noticed something interesting or learned something new in doing this project, please comment on that.
- 8) Note: You may feel free to experiment with the MATLAB radon transform and to check your answers (although not required). However, your solution needs to make use of functions that you have written.

## Description of Problem

Consider the object  $f(x,y) = \text{rect}(x/20)\text{rect}(y/20)\cos(\pi x/2 + \pi y/2)$  where the numbers have units of millimeters. The attenuation coefficient of the object is  $1 \text{ mm}^{-1}$ . The object is imaged with a 1<sup>st</sup> generation CT scanner with a beamwidth of 1mm. The desired FOV is 100 mm.

1. (5 pts.) Label your e-mail, PDF file, and MATLAB code as indicated above.
2. (10 pts.) Make sure that your MATLAB code executes without errors. In addition, all figures should be generated simply by typing the name of the main MATLAB code provided.
3. (5 pts.) Determine the appropriate detector size  $\Delta r$  and the number of radial samples needed to span the FOV. Assume that the middle two samples are acquired at coordinates of  $-\Delta r/2$  and  $\Delta r/2$ .
4. (5 pts.) Determine the number of angular samples required. For the simulations, round this up to the nearest multiple of 4.
5. (5 pts) Sketch the object and label critical points, such as zero-crossing, distance between peaks, etc. Also use MATLAB to plot the image.
6. (20s pts.) **Ignoring** the finite beamwidth, derive an analytical expression for the projections as a function of angle. Using your expression, use MATLAB to generate a sinogram of the object. Note that the sinogram should cover the angles from 0 to  $(N-1)\pi/N$  where N is the number of angular samples. Comment on the features of the sinogram – i.e. why does it look the way it does?
7. (40 pts.) Now consider the effect of the finite beamwidth on your projections. Provide an analytical expression for the projection at 0, 45, and 90 degrees. For all other angles, you may derive analytical expressions or use MATLAB to compute the projections. Your answers should match your analytical expressions at the angle indicated above. If you use MATLAB, describe in detail how you are doing the computation. Use your projections to generate a sinogram of the object. How does this sinogram compare to the one from Part 6? **HINT:** Start with the projections derived in Part 6 and think about how the finite beamwidth affects the projections.
8. (10 pts). Use MATLAB to generate the backprojection of the object using the projections from Part 6. An easy way to do this is to backproject at a projection angle of 0 degrees and then use the MATLAB function **imrotate** to rotate each backprojection. Use the bilinear and crop options in imrotate. Comment on the features of the backprojected image.
9. (20 pts.) Filter the projections from part 6 using both (i) a Ram-Lak filter and (ii) a Hanning windowed filter. Plot and compare the filters and the filtered projections at a projection angle of 45 degrees. Describe the design and the practical implementation of the filters. You will want to use the MATLAB functions conv.m or filter.m.
10. (10 pts.) Now backproject the filtered projections. Comment on features of the filtered backprojection images and on the effect of the choice of filter. Compare to the backprojected images. How does your reconstructed object compare to the original object? Discuss the normalization of the images that is required to get correct estimates of the attenuation coefficients.

11. (10 pts) Using the code you have developed, repeat parts 8 through 10 with the projections from Part 7. How do the reconstructed images compare with those obtained in part 10?

12. (20 pts.) Experiment with acquiring fewer samples in the radial and angular dimensions (e.g. take every 2<sup>nd</sup> sample; take every 4<sup>th</sup> sample). Provide example images (clearly labeled) and comment on what you see. Does changing the bandwidth of the filters help at all? Explain your answer.

13. (20 pts). **Bonus** points. Turn in a reasonable draft solution to parts 3 through 7 on Tuesday November 2, 2010. This will be graded. If your final version differs from your draft solution, indicate this in your final version.

## HINTS ON USING MATLAB

When using MATLAB, it's important to keep in mind that MATLAB really likes vector and matrices. So as much as possible, you want to use vectorized operations (see below). In general, it's a good idea to minimize the use of looping structures (e.g. for loops, while loops). You will need to use some loops for the project, but try to avoid them where possible.

Here are a few examples of how to best use MATLAB.

### Defining a RECT function

**BAD:**

```
i = 1;
for t = -10:0.1:10;
    if t < -1 | t > 1
        rect(i)=0;
    else
        rect(i) = 1;
    end
    i = i+1;
end
```

**Good:**

```
t = -10:0.1:10;
rect = ((t <= 1) & (t >=-1));
```

### Defining a two-dimensional Gaussian function;

**Bad:**

```
i = 1 ; j = 1;
for x = -10:.1:10;
    for y = -10:.1:10;
        g(i,j) = exp(-x^2 -y^2);
        j = j + 1;
    end
    i = i + 1;
end
```

**Good:**

```
[x,y] = meshgrid(-10:.1:10,-10:.1:10);
g = exp(-x.^2 -y.^2);
```
