Today’s Topics

- The concept of spin
- Precession of magnetic spin
- Relaxation
- Bloch Equation
Spin

- Intrinsic angular momentum of elementary particles -- electrons, protons, neutrons.
- Spin is quantized. Key concept in Quantum Mechanics.

The History of Spin

- 1921 Stern and Gerlach observed quantization of magnetic moments of silver atoms
- 1925 Uhlenbeck and Goudsmit introduce the concept of spin for electrons.
- 1933 Stern and Gerlach measure the effect of nuclear spin.
- 1937 Rabi predicts and observes nuclear magnetic resonance.
Classical Magnetic Moment

\[ \vec{\mu} = IA\hat{n} \]

Energy in a Magnetic Field

\[ E = -\vec{\mu} \cdot \vec{B} = -\mu_z B \]

Maximum Energy State

Minimum Energy State
Force in a Field Gradient

\[ \mathbf{F} = -\nabla E = \mu_z \frac{\partial B_z}{\partial z} \]

- Deflected up
- Increasing vertical B-field.
- Deflected down

Stern-Gerlach Experiment

The beam of the atoms of silver

The slit

The furnace with silver

The special shaped magnets

The photographic plate

ms = -(1/2)

ms = +(1/2)

The Stern-Gerlach experiment. On the photographic plate are two clear tracks.
Quantization of Magnetic Moment

The key finding of the Stern-Gerlach experiment is that the magnetic moment is quantized. That is, it can only take on discrete values.

In the experiment, the finding was that

\[ \mu_z = +\mu_0 \text{ OR } -\mu_0 \]
Magnetic Moment and Angular Momentum

A charged sphere spinning about its axis has angular momentum and a magnetic moment.

This is a classical analogy that is useful for understanding quantum spin, but remember that it is only an analogy!

Relation: \( \mu = \gamma S \) where \( \gamma \) is the gyromagnetic ratio and \( S \) is the spin angular momentum.

Quantization of Angular Momentum

Because the magnetic moment is quantized, so is the angular momentum.

In particular, the z-component of the angular momentum is quantized as follows:

\[ S_z = m_s \hbar \]

\[ m_s \in \{-s, -(s-1), ..., s\} \]

\( s \) is an integer or half integer

Hydrogen Proton

Spin $1/2$

$$S_z = \begin{cases} +\hbar/2 \\ -\hbar/2 \end{cases}$$

$$\mu_z = \begin{cases} +\gamma\hbar/2 \\ -\gamma\hbar/2 \end{cases}$$
Boltzmann Distribution

\[ \Delta E = \gamma h B_0 \]

\[ E = \mu_z B_0 \]

\[ E = -\mu_z B_0 \]

\[
\frac{\text{Number Spins Up}}{\text{Number Spins Down}} = \exp(-\Delta E/kT)
\]

Ratio = 0.999990 at 1.5T !!!
Corresponds to an excess of about 10 up spins per million

Equilibrium Magnetization

\[
M_0 = N\langle \mu_z \rangle = N\left(\frac{n_{\text{up}}(-\mu_z) + n_{\text{down}}(\mu_z)}{N}\right)
\]

\[
= N\mu \frac{e^{-\mu_z B/kT} - e^{-\mu_z B/kT}}{e^{\mu_z B/kT} + e^{-\mu_z B/kT}}
\]

\[
= N\gamma^2 \hbar^2 B/(4kT)
\]

N = number of nuclear spins per unit volume
Magnetization is proportional to applied field.

Torque

For a non-spinning magnetic moment, the torque will try to align the moment with magnetic field (e.g. compass needle)

\[ N = \mu \times B \]

Precession

\[ \frac{dS}{dt} = \mu \times B \]
\[ \frac{d\mu}{dt} = \mu \times \gamma B \]

Relation between magnetic moment and angular momentum

\[ \mu = \gamma S \]

Change in Angular momentum
Precession

\[ \frac{d\mu}{dt} = \mu \times \gamma B \]

Analogous to motion of a gyroscope

Precesses at an angular frequency of

\[ \omega = \gamma B \]

This is known as the **Larmor** frequency.

---

Larmor Frequency

\[ \omega = \gamma B \]

Angular frequency in \( \text{rad/sec} \)

\[ f = \gamma B / (2 \pi) \]

Frequency in \( \text{cycles/sec or Hertz} \)

Abbreviated \( \text{Hz} \)

For a 1.5 T system, the Larmor frequency is 63.86 MHz which is 63.86 million cycles per second. For comparison, KPBS-FM transmits at 89.5 MHz.

Note that the earth’s magnetic field is about 50 \( \mu \text{T} \), so that a 1.5T system is about 30,000 times stronger.
Magnetization Vector

\[ M = \frac{1}{V} \sum_{i} \mu_i \]

Vector sum of the magnetic moments over a volume.

For a sample at equilibrium in a magnetic field, the transverse components of the moments cancel out, so that there is only a longitudinal component.

\[ \frac{dM}{dt} = \gamma M \times B \]

Equation of motion is the same form as for individual moments.

RF Excitation

At equilibrium, net magnetization is parallel to the main magnetic field. How do we tip the magnetization away from equilibrium?

\[ B_1 \text{ radiofrequency field tuned to Larmor frequency and applied in transverse (xy) plane induces nutation (at Larmor frequency) of magnetization vector as it tips away from the z-axis.} \]

- lab frame of reference
B₁ induces rotation of magnetization towards the transverse plane. Strength and duration of B₁ can be set for a 90 degree rotation, leaving M entirely in the xy plane.

Images & caption: Nishimura, Fig. 3.3
Relaxation

An excitation pulse rotates the magnetization vector away from its equilibrium state (purely longitudinal). The resulting vector has both longitudinal $M_z$ and tranverse $M_{xy}$ components.

Due to thermal interactions, the magnetization will return to its equilibrium state with characteristic time constants.

- $T_1$ spin-lattice time constant, return to equilibrium of $M_z$
- $T_2$ spin-spin time constant, return to equilibrium of $M_{xy}$

TT. Liu, BE280A, UCSD Fall 2004
Longitudinal Relaxation

\[
\frac{dM_z}{dt} = -\frac{M_z - M_0}{T_1}
\]

After a 90 degree pulse \( M_z(t) = M_0(1 - e^{-t/T_1}) \)

Due to exchange of energy between nuclei and the lattice (thermal vibrations). Process continues until thermal equilibrium as determined by Boltzmann statistics is obtained.

The energy \( \Delta \)E required for transitions between down to up spins, increases with field strength, so that \( T_1 \) increases with \( B \).

T1 Values

Image, caption: Nishimura, Fig. 4.2
Transverse Relaxation

\[
\frac{dM_{xy}}{dt} = -\frac{M_{xy}}{T_2}
\]

Each spin’s local field is affected by the \(z\)-component of the field due to other spins. Thus, the Larmor frequency of each spin will be slightly different. This leads to a dephasing of the transverse magnetization, which is characterized by an exponential decay.

\(T_2\) is largely independent of field. \(T_2\) is short for low frequency fluctuations, such as those associated with slowly tumbling macromolecules.

T2 Relaxation

Free Induction Decay (FID)

After a 90 degree excitation

\[
M_{xy}(t) = M_0 e^{-t/T_2}
\]
T2 Relaxation

Solids exhibit very short $T_2$ relaxation times because there are many low frequency interactions between the immobile spins.

On the other hand, liquids show relatively long $T_2$ values, because the spins are highly mobile and net fields average out.

### T2 Values

Table: adapted from Nishimura, Table 4.2
Example

T₁-weighted  Density-weighted  T₂-weighted

Bloch Equation

\[ \frac{dM}{dt} = M \times \gamma B - \frac{M_x i + M_y j}{T_2} - \frac{(M_z - M_0)k}{T_1} \]

- Precession
- Transverse Relaxation
- Longitudinal Relaxation

i, j, k are unit vectors in the x,y,z directions.
Free precession about static field

\[
\frac{d\mathbf{M}}{dt} = \mathbf{M} \times \gamma \mathbf{B}
\]

\[
= \gamma \begin{vmatrix}
\hat{i} & \hat{j} & \hat{k} \\
M_x & M_y & M_z \\
B_x & B_y & B_z
\end{vmatrix}
\]

\[
= \gamma \begin{pmatrix}
\hat{i}(B_z M_y - B_y M_z) \\
\hat{j}(B_z M_x - B_x M_z) \\
\hat{k}(B_y M_x - B_x M_y)
\end{pmatrix}
\]

Free precession about static field

\[
\begin{bmatrix}
dM_x/dt \\
dM_y/dt \\
dM_z/dt
\end{bmatrix} = \gamma \begin{bmatrix}
B_z M_y - B_y M_z \\
B_x M_z - B_z M_x \\
B_y M_x - B_x M_y
\end{bmatrix}
\]

\[
= \gamma \begin{bmatrix}
0 & B_z & -B_y \\
-B_z & 0 & B_x \\
B_y & -B_x & 0
\end{bmatrix}\begin{bmatrix}
M_x \\
M_y \\
M_z
\end{bmatrix}
\]
Precession

\[
\begin{bmatrix}
\frac{dM_x}{dt} \\
\frac{dM_y}{dt} \\
\frac{dM_z}{dt}
\end{bmatrix} = \gamma
\begin{bmatrix}
0 & B_0 & 0 \\
-B_0 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
M_x \\
M_y \\
M_z
\end{bmatrix}
\]

Useful to define \( M \equiv M_x + jM_y \)

\[
d\frac{dM}{dt} = d\frac{d}{dt}(M_x + iM_y)
= -j\gamma B_0 M
\]

Solution is a time-varying phasor

\[
M(t) = M(0)e^{-j\omega_0 t} = M(0)e^{-j\omega_0 t}
\]

In matrix form this is

\[
\begin{bmatrix}
M_x(t) \\
M_y(t) \\
M_z(t)
\end{bmatrix} =
\begin{bmatrix}
\cos\omega_0 t & \sin\omega_0 t & 0 \\
-\sin\omega_0 t & \cos\omega_0 t & 0 \\
0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
M_x(0) \\
M_y(0) \\
M_z(0)
\end{bmatrix}
\]

The full solution is then a rotation about the z-axis.

\[
M(x(t)) = R_z(\omega_0 t)
\begin{bmatrix}
M_x(0) \\
M_y(0) \\
M_z(0)
\end{bmatrix}
\]
